### MANDAWAR PROJECT, ALIGARH PARGANAH, TONK STATE

Reference.—Para. 39 Report on Irrigation in the Tonk State.

#### REPORT.

Mandawar is a khalsa village, about six miles south-east of Aligarh. The village stands on a high mound, and at the foot of the eastern slope a nullah passes down to the south towards Sop. The tributaries forming this nullah rise about 1½ miles to the north, and unite just above the village, and have cut up the ground in their course, and the land in consequence is broken and unculturable.

Project lescribed.

There is an old naddi on the right bank of the nullah, and also lower down the remains of a broken Dam, but no attempt has been made to bund the nullah itself.

This estimate provides for this, as by forming a small Tank the land, in the bed which is now broken would silt up and become culturable; and the small area of khalsa land below could be irrigated.

The Dam would be entirely of earthwork, so will be most suitable for a relief work even if the project is not carried out before.

2. The catchment area is 2½ square miles, and 10 per cent. of the average rainfall of 25 inches may be calculated on reavailable for storage, or 14.6 m.c.ft.

Catchment Area and Water available for Storage.

3. The following table gives the water-spread and capacity of the proposed Tank at the different contours; R. L. 100 has been taken as the level of the bed of the nullah at the site of the Dam:—

Waterspread and Capacity.

R. L.	Water-spread in s.ft.	Capacity in m.c.ft.
120 115	6,880,000 4,440,000	28.30
113	3,520,000	7.96
110 105	1,960,000 - 560,000	93
100	(Bed lovel).	55

Fit is proposed to make Weir level R. L. 113; the Tank will then have a capacity of 15.45, slightly in excess of the amount estimated as available for storage.

Maximum Discharge and Length of Weir. 4. The maximum discharge from the 2½ square miles of catchment is 1,642 cusecs (Dicken's Formula).

It is proposed to make the Weir at the west end of the Dam 300 ft. in length, by removing a portion of the old breached Dam, and with this length the flood water will spill over, with a head not exceeding 1½ ft. As the soil is light, to prevent cutting away the Weir will consist of a masonry wall 2 ft. thick taken down 3 ft. below the ground surface, then an apron 10 ft. wide of dry stone pitching, 1 ft. deep, with a row of blocks of concrete, each block about 5 ft. × 2 ft. × 3 ft., in rear. The natural surface of the ground on either side the weir will also be pitched up to R. L. 114.50.

The flood water will pass down into the nullah north of the village, as the ground, which is waste land, slopes down very quickly from the site of the Weir.

Dam.

5. The Dam starts from the old breached Dam on the right bank, crosses the nullah, and is continued till high ground on the left bank is reached.

It is 2,850 r.ft. in length, and will consist of earthwork above, with crest R.L. 117.50, or 3 ft. above flood level and 4½ ft. above Weir. The top width is 10 ft., and the front and rear slopes 3 to 1 and 2 to 1 respectively.

Where nullahs are crossed the sand in the bed will be removed for 4 ft. in depth for the whole width of the Dam, and be replaced by good earth.

Sluice.

'6. A Sluice is provided on the left bank of the nullah at chainage 3,600, with sill level R. L. 105; this gives 14.5 m.c.ft. of water available for irrigation, sufficient for 145 acres; and there are about 150 acres of land commanded on this side the nullah, of which 69 acres are khalsa.

The Sluice should be able to give a first watering of 6 inches in 30 days of 12 hours' flow for the whole 145 acres for which there is water when the Tank is full, or  $D = \frac{145 \times 43,560 \times \frac{1}{2}}{30 \times 12 \times 60 \times 60} = \frac{3,150,100}{1,296,000} = 2.4$  cusees; or it should discharge 3.11 m.c.ft. of water during the month.

For the next three months of the Rabi Irrigation season it should be able to discharge the balance of the water required with continuous flow,

or 
$$D = \frac{(14.5 - 3.11)}{3 \times 2.592} = \frac{11.39}{7.776} = 1.46$$
 cusecs.

A 6-inch dia. Sluice will discharge 2.4 cusecs with the mean head of 4 ft., and 1.2 cusecs with a 1-ft. head, so has been provided.

The Sluice consists of a masonry Sluice well, with a Core-wall. Design for for 20 ft. in length in rear on either side, to prevent any chance of the · · water creeping round between the well and the earthen Dam; and is similar in design to the Sluice provided in the Kamaria and Raimanpura Projects for this Parganah.

The foundations are taken down a depth equal to half the depth of the water against the face of the Dam, and consist of a bed of concrete 3 ft. thick on which the masonry flooring will be built.

The Irrigation Channel has been set out for 6300 r.ft. in length, with a fall of 1 ft. per mile. To discharge 2 4 cusecs it must have a bed. width of 2 ft., depth of  $1\frac{1}{2}$  ft., and side slopes of 1 to 1.

The following is the Abstract Estimate of cost of the Project:

	2,	,			${f Rs.}$
ı.	Dam			••	5,716
2.	Weir	•••	Sire.	4, 149,	1,135
3.	Sluice	• •••	. £	•••	961
4.	Irrigation Cha	nnel	•••	•••	132
5.	Contingencies	***	***	•••	397
			Total	• • •	8,341

10. If all the 145 acres, for which there is water when the Tank is Revenue. full, are irrigated, allowing Rs. 4 per acre—the difference of assessment & between irrigated and unirrigated land in the Parganah-a revenue of Rs. 580 would be realized, or a profit of nearly 7 per cent on the outlage?

- Stone and lime will have to be brought from Sop, a distance of 11. Materials. two miles.
- The surveys were made by Sub-Overseer Sham Singh and the Plans and Estimate worked out by Overseer Mannu Lal, under the directions of the Superintending Engineer, Protective Irrigation Works, Rajputana.

Prepara-Project.

٠.

Earthwork.

#### SPECIFICATION.

- All the dimensions and measurements of the work are given in Dimensions the Plans and Estimate, and are to be strictly adhered to.
- The centre line and slopes of Dam to be marked out with Marking out. trenches 1 ft. deep and 1 ft. broad, showing permatically the inner and outer slopes and the breadth of the top of embankment.
- Before any new earth is commenced the old surface to be carefully picked up at least 9 inches and all roots and grass removed. The new earth to be then thrown down in 9-inch layers and each layer carefully consolidated before the next is commenced. No clods to be allowed. All layers to be laid concave, that is lower in the centre. No earth to be excavated within 100 ft. of either toe of the slope.

Masonry.

16. The masonry of the Weir, and outlet Sluice, to be of rubble stone set in lime mortar; only hard and durable stones to be used, and the masonry to be kept wet during construction. All the stones to be hammer-dressed and to break joint in the same as well as in the successive courses.

All stones are to be laid on their natural beds; where there is batter the beds of the stones are to be at right angles to the batter. Hollows between the larger stones to be filled in with smaller ones completely embedded in mortar. No empty hollow to be left, nor spaces filled wholly with mortar or rubbish where pieces of stones ought to have been inserted.

The faces of the masonry in contact with the earth to be left quite rough, and those remaining exposed to be smoothed and pointed with lime mortar.

Concrete. ;

- in 6-inch layers and well consolidated.
- Lime Mortar. Mortar to consist of 1 part lime to 1½ parts clear sand or surked the lime to be of good hard kunkar burnt in wood-fuel, cow-dung to be only used for igniting the fire.

F. St.-G. MANNERS SMITH,
Superintending Engineer,
Protective Irrigation Works, Rajputana.

AJMER.

Dated 11th August 1905.
